The source category Solid fuels (1.B.1) consists of two sub-source subcategories – the source subcategory Coal mining (1.B.1.a) nad the source subcategory Coal transformation (1.B.1.b). This chapter discusses fugitive emissions from coal mining, coal handling, including door leakages from coke ovens and quenching (emissions from the furnace are covered by category 1.A.1.c), and emissions from the beneficiation of solid fuels. In the mining sector, a distinction is made between open-pit mines, in which raw materials are extracted from pits open to the surface, and closed-pit mines, in which seams are mined underground. In Germany, hard coal used to be mined in closed-pits only (until 2018), while lignite is mined in four coal fields since 2003 with the open-pit method only.

Lignite production

The activity rates for lignite production have been taken from the *Statistik der Kohlenwirtschaft*'s website (in German only) [9]. Extracted coal is moved directly to processing and to power stations. The emission factors used for calculating emissions from lignite production (TSP, PM_{10} and $PM_{2.5}$) already include possible emissions from transport and storage. They are taken from a 2006 research project [1] and the CEPMEIP-Database [2].

Activity data	Unit	1990	1995	2000	2005	2010	2015	2018	2019
Extraction of lignite	Mt	357	193	168	178	169	178	166	131

Source of emission factor	Substance	Unit	Value
Extraction of lignite	TSP	kg/t	0.05086
Extraction of lignite	PM_{10}	kg/t	0.025
Extraction of lignite	$PM_{2.5}$	kg/t	0.00375

Hard coal coke production

The activity rates for hard coal coke production have been taken from the *Statistik der Kohlenwirtschafts*'s website (in German only) [9]. The emission factors for hard coal coke production have been obtained from the research project "Emission factors for the iron and steel industry, for purposes of emissions reporting" ("Emissionsfaktoren zur Eisen- und Stahlindustrie für die Emissionsberichterstattung") [3].

Source	Substance	Unit	Value
Production of hard-coal coke	CO	kg/t	0.015
Production of hard-coal coke	NH_3	kg/t	0.000243
Production of hard-coal coke	NMVOC	kg/t	0.096
Production of hard-coal coke	SO_2	kg/t	0.004
Production of hard-coal coke	TSP	kg/t	0.011
Production of hard-coal coke	PM_{10}	kg/t	0.004
Production of hard-coal coke	$PM_{2.5}$	kg/t	0.004

There are many potential sources of PAH emissions from coking plants. The dominant emission sources are leakages from coke oven doors and from charging operations. As there is limited data available on PAH emissions, the uncertainties of the estimated emission factors are very high. It should also be taken into account that emissions from coke production greatly vary between different coke production plants. The emission factors for benzo[a]pyrene and mixed PAH have been revised by research projects in 2010 [4,5]. Split factors for Black Carbon (BC) are based on the EMEP Guidebook 2016 [6].

Charcoal production

Small quantities of charcoal are produced in Germany – by one major charcoal-factory operator and in a number of demonstration charcoal kilns. The pertinent quantities are determined by the Federal Statistical Office and are subject to confidentiality requirements. The emission factors were obtained from US EPA 1995 [7] . Use of charcoal is reported under 2.G.4.

Decommissioned hard-coal mines

NMVOC Emissions from decommissioned hard-coal mines play a role in this sub- source subcategory. When a hard-coal mine is decommissioned, mine gas can escape from neighbouring rock, and from coal remaining in the mine, into the mine's network of shafts and passageways. Since the mine is no longer artificially ventilated, the mine gas collects and can then reach the surface via gas pathways in the overlying rock or via the mine's own shafts and passageways. Such mine gas was long seen

primarily as a negative environmental factor. Recently, increasing attention has been given to the gas' positive characteristics as a fuel (due to its high methane content, it is used for energy recovery). In the past, use of mine gas was rarely cost-effective. This situation changed fundamentally in 2000 with the Renewable Energy Sources Act (EEG). Although mine gas is a fossil fuel in finite supply, its use supports climate protection, and thus the gas was included in the EEG. The Act requires network operators to accept, and provide specified compensation for, electricity generated with mine gas and fed into the grid. The NMVOC emissions from decommissioned hard-coal mines have been calculated in the research project “Potential for release and utilisation of mine gas” (“Potential zur Freisetzung und Verwertung von Grubengas”) [8]. The relevant calculations were carried out for all mining-relevant deposits in Germany.

Source of emission factor	**Substance**	unit	Value
decommissioned hard-coal mines	NMVOC	kg/m³	0.001599
